

NAME

rgbasm — Game Boy assembler

SYNOPSIS

```
rgbasm [-EhVvw] [-b chars] [-D name[=value]] [-g chars] [-I path]
        [-M depend_file] [-MG] [-MC] [-MP] [-MT target_file] [-MQ target_file]
        [-o out_file] [-P include_file] [-p pad_value] [-Q fix_precision]
        [-r recursion_depth] [-s features:state_file] [-W warning]
        [-X max_errors] asmfile
```

DESCRIPTION

The **rgbasm** program creates an RGB object file from an assembly source file. The object file format is documented in *rgbds*(5).

The input *asmfile* can be a path to a file, or `-` to read from standard input.

Note that options can be abbreviated as long as the abbreviation is unambiguous: `--verb` is `--verbose`, but `--ver` is invalid because it could also be `--version`. The arguments are as follows:

- `-b chars`, `--binary-digits chars`
 Allow two characters to be used for binary constants in addition to the default ‘0’ and ‘1’. Valid characters are numbers other than ‘0’ and ‘1’, letters, ‘.’, ‘#’, or ‘@’.
- `-D name[=value]`, `--define name[=value]`
 Add a string symbol to the compiled source code. This is equivalent to *name* **EQU** “*value*” in code, or *name* **EQU** “1” if *value* is not specified.
- `-E`, `--export-all`
 Export all labels, including unreferenced and local labels.
- `-g chars`, `--gfx-chars chars`
 Allow four characters to be used for graphics constants in addition to the default ‘0’, ‘1’, ‘2’, and ‘3’. Valid characters are numbers other than ‘0’ to ‘3’, letters, ‘.’, ‘#’, or ‘@’. The defaults are 0123.
- `-h`, `--help`
 Print help text for the program and exit.
- `-I path`, `--include path`
 Add a new “include path”; *path* must point to a directory. When any **INCLUDE** (including the implicit one from `-P`), **INCBIN**, or **READFILE** is attempted, **rgbasm** first looks up the provided path from its working directory; if this fails, it tries again from each of the “include path” directories, in the order they were provided.
- `-M depend_file`, `--dependfile depend_file`
 Write *make*(1) dependencies to *depend_file*.
- `-MG`
 To be used in conjunction with `-M`. This makes **rgbasm** assume that missing files are auto-generated: when any **INCLUDE** (including the implicit one from `-P`), **INCBIN**, or **READFILE** is attempted on a non-existent file, it is added as a dependency, then **rgbasm** exits normally or continues processing (depending on whether `-MC` was enabled) instead of erroring out. This feature is used in automatic updating of Makefiles.
- `-MC`
 Implies `-MG`. This makes **rgbasm** continue processing after a non-existent dependency file, instead of exiting. Note that this *is not* recommended if any non-existent dependencies would have influenced subsequent processing, e.g. by causing an **IF** condition to take a different branch.
- `-MP`
 When enabled, this adds a phony target to the rules emitted by `-M` for each dependency other than the main file. This prevents *make*(1) from erroring out when dependency files are deleted.

- MT *target_file*
Add a target to the rules emitted by -M. The exact string provided will be written, including spaces and special characters.
-MT fileA -MT fileB
is equivalent to
-MT 'fileA fileB'.
If neither this nor -MQ is specified, the output file name is used.
- MQ *target_file*
Same as -MT, but additionally escapes any special *make*(1) characters, essentially '\$'.
- o *out_file*, --output *out_file*
Write an object file to the given filename.
- P *include_file*, --preinclude *include_file*
Pre-include a file. This acts as if a **INCLUDE** "*include_file*" was read before the input *asmfile*.
- p *pad_value*, --pad-value *pad_value*
Use this as the value for **DS** directives in ROM sections, unless overridden. The default is 0x00.
- Q *fix_precision*, --q-precision *fix_precision*
Use this as the precision of fixed-point numbers after the decimal point, unless they specify their own precision. The default is 16, so fixed-point numbers are Q16.16 (since they are 32-bit integers). The argument may start with a '.' to match the Q notation, for example, -Q .16.
- r *recursion_depth*, --recursion-depth *recursion_depth*
Specifies the recursion depth past which **rgbasm** will assume being in an infinite loop. The default is 64.
- s *features:state_file*, --state *features:state_file*
Write the specified *features* to *state_file*, based on the final state of **rgbasm** at the end of its input. The expected *features* are a comma-separated subset of the following:
 - equ Write all numeric constants as **def** *name* **equ** *value*.
 - var Write all variables as **def** *name* **=** *value*.
 - equs Write all string constants as **def** *name* **equus** "*value*".
 - char Write all characters as **charmap** *name*, *value*.
 - macro Write all macros as **macro** *name* ... **endm**.
 - all Acts like *equ*, *var*, *equis*, *char*, *macro*.

This flag may be specified multiple times with different feature subsets to write them to different files (see "EXAMPLES" below).
- V, --version
Print the version of the program and exit.
- v, --verbose
Be verbose.
- W *warning*, --warning *warning*
Set warning flag *warning*. A warning message will be printed if *warning* is an unknown warning flag. See the "DIAGNOSTICS" section for a list of warnings.
- w
Disable all warning output, even when turned into errors.
- X *max_errors*, --max-errors *max_errors*
If more than this number of errors (not warnings) occur, then abort the assembly process; -X 0 disables this behavior. The default is 100 if **rgbasm** is printing errors to a terminal, and 0

otherwise.

DIAGNOSTICS

Warnings are diagnostic messages that indicate possibly erroneous behavior that does not necessarily compromise the assembling process. The following options alter the way warnings are processed.

`-Werror`

Make all warnings into errors. This can be negated as `-Wno-error` to prevent turning all warnings into errors.

`-Werror=`

Make the specified warning or meta warning into an error. A warning's name is appended (example: `-Werror=obsolete`), and this warning is implicitly enabled and turned into an error. This can be negated as `-Wno-error=` to prevent turning a specified warning into an error, even if `-Werror` is in effect.

The following warnings are “meta” warnings, that enable a collection of other warnings. If a specific warning is toggled via a meta flag and a specific one, the more specific one takes priority. The position on the command-line acts as a tie breaker, the last one taking effect.

`-Wall`

This enables warnings that are likely to indicate an error or undesired behavior, and that can easily be fixed.

`-Wextra`

This enables extra warnings that are less likely to pose a problem, but that may still be wanted.

`-Weverything`

Enables literally every warning.

The following warnings are actual warning flags; with each description, the corresponding warning flag is included. Note that each of these flags also has a negation (for example, `-Wcharmap-redef` enables the warning that `-Wno-charmap-redef` disables; and `-Wall` enables every warning that `-Wno-all` disables). Only the non-default flag is listed here. Ignoring the “no-” prefix, entries are listed alphabetically.

`-Wno-assert`

Warn when **WARN**-type assertions fail. (See “Aborting the assembly process” in *rgbasm(5)* for **ASSERT**).

`-Wbackwards-for`

Warn when **FOR** loops have their start and stop values switched according to the step value. This warning is enabled by `-Wall`.

`-Wbuiltin-args`

Warn about incorrect arguments to built-in functions, such as **STRSLICE**() with indexes outside of the string's bounds. This warning is enabled by `-Wall`.

`-Wcharmap-redef`

Warn when re-defining a charmap mapping. This warning is enabled by `-Wall`.

`-Wdiv`

Warn when dividing the smallest negative integer (-2^{31}) by -1, which yields itself due to integer overflow.

`-Wempty-macro-arg`

Warn when a macro argument is empty. This warning is enabled by `-Wextra`.

`-Wempty-strrpl`

Warn when **STRRPL**() is called with an empty string as its second argument (the substring to replace). This warning is enabled by `-Wall`.

- Wlarge-constant
Warn when a constant too large to fit in a signed 32-bit integer is encountered. This warning is enabled by -Wall.
- Wmacro-shift
Warn when shifting macro arguments past their limits. This warning is enabled by -Wextra.
- Wno-nested-comment
Warn when the block comment start sequence ‘/*’ is found inside of a block comment. Block comments cannot be nested, so the first ‘*/’ will end the whole comment.
- Wno-obsolete
Warn when obsolete features are encountered, which have been deprecated and may later be removed.
- Wnumeric-string=
Warn when a multi-character string is treated as a number. -Wnumeric-string=0 or -Wno-numeric-string disables this warning. -Wnumeric-string=1 or just -Wnumeric-string warns about strings longer than four characters, since four or fewer characters fit within a 32-bit integer. -Wnumeric-string=2 warns about any multi-character string.
- Wpurge=
Warn when purging symbols which are likely to have been necessary. -Wpurge=0 or -Wno-purge disables this warning. -Wpurge=1 or just -Wpurge warns when purging any exported symbol (regardless of type). -Wpurge=2 also warns when purging any label (even if not exported).
- Wshift
Warn when shifting right a negative value. Use a division by 2**N instead.
- Wshift-amount
Warn when a shift’s operand is negative or greater than 32.
- Wtruncation=
Warn when an implicit truncation (for example, **db** to an 8-bit value) loses some bits. -Wtruncation=0 or -Wno-truncation disables this warning. -Wtruncation=1 warns when an N-bit value is 2**N or greater, or less than -2**N. -Wtruncation=2 or just -Wtruncation also warns when an N-bit value is less than -2**(N-1), which will not fit in two’s complement encoding.
- Wunmapped-char=
Warn when a character goes through charmap conversion but has no defined mapping. -Wunmapped-char=0 or -Wno-unmapped-char disables this warning. -Wunmapped-char=1 or just -Wunmapped-char only warns if the active charmap is not empty. -Wunmapped-char=2 warns if the active charmap is empty, and/or is not the default charmap ‘main’.
- Wunmatched-directive
Warn when a **PUSHC**, **PUSHO**, or **PUSHS** directive does not have a corresponding **POPC**, **POPO**, or **POPS**. This warning is enabled by -Wextra.
- Wunterminated-load
Warn when a **LOAD** block is not terminated by an **ENDL**. This warning is enabled by -Wextra.
- Wno-user
Warn when the **WARN** built-in is executed. (See “Aborting the assembly process” in *rgbasm(5)* for **WARN**).

EXAMPLES

You can assemble a source file in two ways.

Straightforward way:

```
$ rgbasm -o bar.o foo.asm
```

Pipes way:

```
$ cat foo.asm | rgbasm -o bar.o -
```

```
$ rgbasm -o bar.o - < foo.asm
```

The resulting object file is not yet a usable ROM image—it must first be run through *rgbblink*(1) and then *rgbfix*(1).

Writing the final assembler state to a file:

```
$ rgbasm -s all:state.dump.asm foo.asm
```

Or to multiple files:

```
$ rgbasm -s equ,var:numbers.dump.asm -s equ:strings.dump.asm  
foo.asm
```

BUGS

Please report bugs on *GitHub*: <https://github.com/gbdev/rgbds/issues>.

HISTORY

rgbasm was originally written by Carsten Sørensen as part of the ASMotor package, and was later repackaged in RGBDS by Justin Lloyd. It is now maintained by a number of contributors at <https://github.com/gbdev/rgbds>.
